

Why the window is sharp: the first walk that one census sees and the other does not

inside the window: $k = g$

the only walk the tree cannot explain
is the cycle itself

no lift ✓ non-backtracking ✓
counted by BOTH censuses

one step past it: $k = g + 2$

the lollipop: wrap the cycle,
then the tail out and back

no lift ✓ non-backtracking ×
counted by ONE census only — the law breaks
